Appendix X. Pasco Breadboard
Revised July 18, 2003

We will use Pasco circuit boards in several experiments. You should examine the board carefully and understand how to connect resistors and other components to the board and its battery. The board includes 8 pads, each with two electrically-joined spring connectors mounted at right angles to each other.

Figure 1 illustrates four of these pads with resistors $R_1$, $R_2$ and $R_3$ mounted in the springs. The tops of $R_1$ and $R_2$ are electrically connected to each other and to the left side of $R_3$. Likewise the bottoms of $R_1$ and $R_2$ are connected to each other. Wire $a$ is connected to the bottom of $R_1$ and $R_2$ while wire $b$ is connected to the right side of $R_3$.

This circuit has $R_1$ and $R_2$ connected in parallel and the combination is in series with $R_3$. Figure 2 is a schematic diagram of the same circuit with wires $b$ and $a$ connected to the positive and negative terminals of a battery respectively.

Pushbutton switches have been installed on both sides of the Pasco board, between the rows of pads. When pressed, these switches will make an electrical contact between the pad directly above and directly below the switch. This connection is only made while the button is held down; when released, the connection is lost. Note the battery connectors on the board, indicated by the cell symbols. For some experiments, we may wish to connect the two cells in series to form a 3 V battery. Figure 3 shows such a connection with the two cells in series providing a potential difference across a resistor chain.

To conserve the batteries, disconnect one lead (for example, lead $a$ in Figure 3) from your circuit when you are not making measurements.
